Contemporary total knee arthroplasty demands high performance instrumentation that provides enhanced efficiency, precision, and flexibility. Through a programme of continuous development, DePuy Orthopaedics now offers a single system of High Performance instruments that supports your approach to knee replacement surgery.

This surgical technique provides instruction on the implantation of the LCS® family of rotating platform knees.

There are several approach options available to the surgeon, the most common are: medial parapatellar, mini-midvastus and mini-subvastus.
Surgical Summary

Step 1: Incision and exposure

Step 2: Patellar resection

Step 3: Lower leg alignment

Step 7: Long leg alignment

Step 8: Femoral rotation and A/P resection

Step 9: Flexion gap assessment

Step 13: Final component implantation
Step 4: Tibial resection
Step 5: Femoral sizing
Step 6: I.M. hole preparation
Step 10: Distal femoral resection
Step 11: Final femoral preparation
Step 12: Trial reduction
Incision and Exposure

The LCS High Performance instrumentation is designed for use with and without CI™ computer assisted surgery, for both open and less invasive approaches to the knee.

Make a straight midline skin incision starting from 2 to 4 cm above the patella, passing over the patella, and ending at the tibial tubercle (Figure 1). The three most common approach options for the surgeon are: medial parapatellar, mini-midvastus, and mini-subvastus.

For surgeons choosing the medial parapatellar (Figure 2):
Make a medial parapatellar incision through the retinaculum, the capsule and the synovium, with neutral alignment or with varus deformity. The medial parapatellar incision starts proximal (4 cm) to the patella, incising the rectus femoris tendon longitudinally, and continues distally around the medial aspect of the patella and ligamentum patellae stopping just medial to the tibial tubercle (Figure 2). Following this incision, either evert or luxate the patella laterally to expose the entire tibio-femoral joint.
Incision and Exposure

For surgeons choosing the mini-midvastus option (Figure 3):
The midvastus approach starts 3-4 cm in the middle of the Vastus Medialis Obliquus (VMO), running distal and lateral to the muscle fibres towards the rectus femoris, splitting the VMO.

Continue the incision distally around the medial aspect of the patella and ligamentum patellae stopping just medial to the tibial tubercle (Figure 3). Following this incision, luxate the patella laterally to expose the entire tibio-femoral joint.

For surgeons choosing the subvastus option (Figure 4):
The subvastus approach starts by lifting the VMO with a 90 degree stomp hook. A 3-4 cm incision is made in the capsule underneath the VMO, running horizontal from medial to lateral towards the mid portion of the patella. The incision continues distally around the medial aspect of the patella and ligamentum patellae stopping just medial to the tibial tubercle. Following this incision, luxate the patella laterally to expose the entire tibio-femoral joint.
Excise hypertrophic synovium if present and a portion of the infrapatellar fat pad to allow access to the medial, lateral and intercondylar spaces.

Remove all osteophytes at this stage as they can affect soft tissue balancing (Figure 5).

*Note: Particular attention should be given to posterior osteophytes as they may affect flexion contracture or femoral rotation.*

Evaluate the condition of the posterior cruciate ligament (PCL) and resect the PCL if required.
Patellar Resection

Resection and preparation of the patella can be performed sequentially or separately, as desired, and can be performed at any time during surgery.

Measure the thickness of the patella and calculate the level of bone resection (Figure 6). The thickness of the resurfaced patella should be the same as the natural patella. There should be equal amounts of bone remaining in the medial / lateral and superior / inferior portions of the patella.

Select a patellar stylus that matches the thickness of the implant to be used. Slide the appropriate size stylus into the saw capture of the resection guide. The minimum depth of the patellar resection should be no less than 10 mm (Figure 7).

However, when the patella is small, a minimal residual thickness of 12 mm should be maintained to avoid fracture.

A 12 mm remnant stylus can be attached to the resection guide resting on the anterior surface of the patella, to avoid over resection (Figure 8).

Place the leg in extension and position the patellar resection guide with the sizing stylus against the posterior cortex of the patella with the serrated jaws at the superior and inferior margins of the articular surface. Close the jaws to firmly engage the patella (Figure 9).

Example: for a standard patella 25 mm thick, resect 11.6 mm of articular surface, leaving 13.4 mm of residual bone to accommodate the 10.9 mm thickness implant.
Tilt the patella laterally to an angle of 40 to 60 degrees (Figure 10).

Remove the stylus and perform the resection using an oscillating saw through the saw capture and flush with the cutting surface (Figure 11).

A patellar wafer can be hand placed on the resected surface if required, to protect the patellar bone bed.
The tibia can now be resected to create more room in the joint space.

Assemble the appropriate 7 degree, left / right or symmetrical cutting block to the tibial jig uprod. Slide the tibial jig uprod into the ankle clamp assembly (Figure 12).

For tibial resection using intramedullary alignment, see Appendix A. For tibial resection using spiked uprod, see Appendix B.

Figure 12
Place the knee in 90 degrees of flexion with the tibia translated anteriorly and stabilised. Place the ankle clamp proximal to the malleoli (Figure 13). Align the proximal central marking on the tibia cutting block with the medial one third of the tibial tubercle to set rotation (Figure 14).

To provide stability, insert a central pin through the vertical slot in the cutting block (Figure 15). Push the quick release button to set the approximate resection level (Figure 16).

**Varus / Valgus**
Align the tibial jig ankle clamp parallel to the transmalleolar axis to establish rotational alignment (Figure 15). The midline of the tibia is approximately 3 mm medial to the transaxial midline. Translate the lower assembly medially (usually to the second vertical mark), by pushing the varus / valgus adjustment wings (Figure 15). There are vertical scribe marks for reference aligning to the middle of the talus.

**Slope**
The tibial jig uprod and ankle clamp are designed to prevent an adverse anterior slope. On an average size tibia this guide gives approximately a 7 degree (Figure 17) tibial slope when the slope adjustment is translated posteriorly until it hits the stop.

*Note: This may not give a true 7 degree slope.*
The angle of the tibial slope can be increased to greater than 7 degrees should the patient have a greater natural slope (Figure 17). First, unlock the slide locking position and then translate the tibial slope adjuster anteriorly until the desired angle is reached.

As each patient’s anatomy varies, the tibial jig uprod can be used for both smaller and larger patients. The length of the tibia influences the amount of slope when translating the adapter anteriorly. The 7 degree default position can be overridden by pressing the slope override button and moving the slope adjustment closer to the ankle.

On the uprod 5, 6 and 7 zones are present, which correspond to the length of the tibia. These markings can be used to fine tune the amount of slope.

When the uprod shows a zone marked “7” this indicates that when the lower assembly is translated 7 mm anterior, it will give an additional 1 degree of posterior slope (Figure 18).
Height
When measuring from the less damaged side of the tibial plateau set the stylus to 8 mm or 10 mm. If the stylus is placed on the more damaged side of the tibial plateau, set the stylus to 0 mm or 2 mm.

Adjustment of resection height on the stylus should be done outside the joint space before locating the stylus in the cutting block.

If planning to resect through the slot, position the foot of the tibial stylus marked “slotted” into the slot of the tibial cutting block (Figure 19). If planning to resect on top of the cutting block, place the foot marked “non-slotted” into the cutting slot.

Note: There is a 4 mm difference between the top of the tibial cutting block and the slot.

The final resection level can be dialled in by rotating the fine-tune mechanism clockwise (upward adjustment) or counterclockwise (downward adjustment). Care should be taken with severe valgus deformity, not to over resect the tibia.
Tibial Resection

After the height has been set, pin the block through the 0 mm set of holes (the stylus may need to be removed for access). +/-2 mm pinholes are available on the resection blocks to further adjust the resection level where needed.

The block can be securely fixed with a convergent pin. Resect the tibia using a 1.47 mm saw blade (Figure 20) and remove the resected bone.

Remove the central pin from the slot and divergent locking pin if used. The remaining tibial pins may be left in place to aid alignment during the procedure.

Check the depth and accuracy of the bone cut before removing the tibial cutting block. A 2 degree varus / valgus recut block is available if required.
Femoral Sizing

Size the femur using either the femoral templates or the femoral sizing calliper. If the femoral template is used, the template that corresponds in size to the outer profile of the femoral condyle will indicate the size of femoral component to be selected (Figure 21). It is important to use the condyle that is least affected to reference the femoral size. This may be the lateral condyle in varus knees and the medial condyle in valgus knees. Any osteophytes compromising the sizing should be removed.

Alternatively, assess the M/L and A/P dimensions using the sizing calliper (Figures 22 and 23). The fixed end of the sizing calliper rests on the medial condyle and provides a direct measurement of implant size. The reverse face of the calliper is marked in millimetres.

The anterior femoral cortex is an important reference for sizing, as the final femoral component must be seated here.

I.M. Hole Preparation

Depress the sizing button and slide the I.M. hole locator until the chosen femoral size appears directly above the line (Figure 24). Position the yoke beneath the muscle anteriorly, on the periosteum, and centre the device on the anterior femoral shaft.

An extramedullary alignment rod can be placed through the handle of the I.M. hole locator to aid alignment.

Carefully position the I.M. hole locator between the epicondyles. The position of the femoral I.M. hole is generally 3-5 mm medial to the apex of the intercondylar notch and 7-10 mm anterior to the origin of the PCL. Drawing a centring mark or Whiteside’s Line and the preoperative X-ray may be useful to assist precise location of the I.M. hole (Figure 25).

At this moment the ultimate rotational position of the femoral implant is not yet defined. Pins can be placed in the I.M. hole locator to assist with additional stability. The device may also be lightly impacted onto the distal femur for additional stability.

Open up the I.M. canal on the distal femur using the 9 mm I.M. starter drill (Figure 26).

Take care to ensure that the drill avoids the cortices. The drill may be toggled slightly to prevent over-pressurisation of the I.M. canal.

*Excessive toggling may result in an overly wide I.M. hole and should be avoided.*

Remove the pins, then the I.M. hole locator and clear the canal of fat and fluid.
Select the appropriate I.M. plate (3-8 degree angle) as determined during preoperative X-ray analysis. Insert the I.M. plate into the distal femoral I.M. canal taking care to avoid over-pressurisation (Figure 27).

Place the knee in full extension. Insert a 10 mm spacer block onto the I.M. plate and into the extension space to assess alignment (Figure 28).

The surgeon should be aware that the I.M. canal is providing an approximation of the correct anatomic axis.

The extension gap must be rectangular in configuration with the leg in full extension. If the gap is not rectangular the extension gap is not balanced and appropriate soft tissue balancing must be performed.

Equal medial and lateral lift-off should not exceed 3-5 mm. This is visually assessed by judging the position of the I.M. plate relative to the tibial resection.

The extramedullary alignment rod attached through the spacer block handle may be helpful in assessing alignment (Figure 29).

If the extension gap is too small for the standard 10 mm block, the 4 mm spacer block can be used. If this is required, additional proximal tibial resection may be indicated. The most common cause for a tight extension gap is the presence of a fixed flexion contracture. This may be caused by posterior femoral osteophytes or a contracture of the capsule itself. In this case, removal of the osteophytes or release of the capsule may be indicated.
A/P Block Assembly

Remove the spacer block and return the knee joint to flexion with the I.M. plate still within the I.M. canal. **If an angled I.M. plate was not used during long leg alignment, select the 0 Degree I.M. plate and insert into the I.M. canal.** Assemble the femoral stylus to the appropriate size A/P resection block (Figure 30).

*The stylus is fully inserted into the anterior slot on the A/P block and references the level of the final anterior cut.* Ensure the A/P resection block is unlocked and lower the assembly onto the I.M. plate. Translate the block posteriorly until the anterior femoral stylus contacts the anterior cortex of the femur.

*The stylus should rest on the anterior femur at the approximate exit point of the anterior cut (Figure 30).* If the recommended anterior cut is either suggesting notching the anterior femoral cortex, or cutting air above the anterior femoral cortex, the A/P resection block can be adjusted anteriorly, or posteriorly, in 1.25 mm increments using the scale as a reference.

*Fix the position of the A/P resection block by turning the locking mechanism (Figure 31).* The AP locking handle shown in Figure 31 can be used to help secure the lock. Final rotation has not been fixed at this stage. Remove the anterior femoral stylus.

**Figure 30**

**Figure 31**
Introduce the femoral guide positioner into the joint space engaging the middle slot of the A/P resection block (Figure 32). The knee may be slightly flexed or extended until the positioner lies flat on the previously resected proximal tibia.

If the collateral ligaments are balanced and the joint space is too tight to accept the femoral guide positioner, the tibial cut and chosen A/P size may need to be reviewed. If too tight, the tibial cutting block can be placed back onto the tibial fixation pins, selecting a more proximal row of holes, lowering the block and resecting additional proximal tibial bone.

If the joint space is too lax, tibial shims may be added to ensure that the positioner fits snugly (Figure 33). If tibial shims greater than 15 mm are required to remove the laxity in flexion, the A/P sizing may need to be re-evaluated. If required, the femoral component may be upsized or downsized at this stage, by selecting the next sized A/P resection block and sliding it onto the I.M. plate.

The A/P femoral resection blocks are anterior-referencing (i.e. the same distance from the anterior cutting surface regardless of component size) so any additional resection will remove bone from the posterior condyles.
A/P Resection

Note that down sizing by one size will result in approximately 5 mm more bone being removed from the posterior condyles, effectively increasing the flexion gap by 5 mm. Re-evaluate the tibial alignment using the external alignment rod, passed through the hole in the femoral guide positioner (Figure 34).

The femoral rotation is set by the femoral guide positioner and is based on the principle of equal compartment tension and balanced collateral ligaments. Using the femoral guide positioner this balance should automatically occur, because the femur can freely rotate around the I.M. plate.

Rotation is correct when the collateral ligaments are tensioned and balanced. Conduct a final check of the anterior resection level with the visualisation wing. **All adjustments should be made prior to pinning the block. Pin the A/P resection block to the distal femur using the two neutral central holes (marked with a square) before cutting.**

Remove the femoral guide positioner. Resect the anterior cortex through the slots using a 1.47 mm saw blade (Figure 35) and remove the resected bone. The final size of the femoral component can be checked and changed if necessary. The posterior femoral condyles are then resected.
Once the resections are completed, remove the pins, cutting block and I.M. plate.

To measure the flexion gap, insert the spacer block assembly into the flexion gap.

The assembly consists of a 10 mm base handle (equivalent to the final tibial baseplate and tibial insert thickness) plus a femoral shim (equivalent to the thickness of the femoral condyle on the implant) (Figure 36).

Assess medial and lateral tension, as the compartments should be equal. If necessary, a tibial shim may be added to the spacer block (Figure 37).

Make a note of the thickness of the spacer block utilised for the flexion gap. This will subsequently determine the extension gap.
Preoperative X-rays are used to define the angle between the femoral anatomical and mechanical axes.

**Femoral Alignment**

Set the distal femoral alignment guide to the appropriate valgus angle (3-8 degrees) determined during preoperative X-ray analysis and lock the guide (Figure 38).

Attach the T-handle to the I.M. rod and slowly introduce the rod into the medullary canal, to the level of the isthmus (Figure 39).

The T-handle is removed and the distal femoral alignment guide is placed on the I.M. rod (Figure 40).
The distal femoral outrigger and distal cutting block are assembled and then lowered down through the distal femoral alignment guide (Figures 41, 42 and 43).

The distal cutting block must have the pop-up saw capture open to assemble onto the distal femoral outrigger. The pop-up saw capture can be opened by inserting a sawblade into the slot.

The distal femoral alignment guide should be placed into the notch of the femur.

*It is important that the body of the distal cutting block remains flush on the anterior femoral cut (Figure 43).*
Distal Cutting Block and Valgus Assessment

Ensure the body of the distal cutting block is flat on the anterior femur before pinning through the neutral 0 mm pin holes. This will allow +2.5 or –2.5 mm adjustments to be made if required. Pre-drilling is recommended. The distal femoral outrigger is removed from the distal femoral alignment guide and distal cutting block.

Replace the T-handle onto the I.M. rod and remove the distal femoral alignment guide and I.M. rod, leaving the distal cutting block pinned to the anterior cortex (Figure 44).

Assess varus / valgus alignment using the external alignment tower. With the femur in extension and in neutral rotation, correct alignment is indicated when the proximal end of the external alignment rod is centred over the head of the femur, or approximately two finger breadths medial to the anterior superior iliac spine (Figure 45).

If alignment is found to be other than desired, adjust the valgus angle by reassembling the femoral alignment guide and outrigger to the distal cutting block. Alternatively, the distal varus / valgus 2 degree recut block can be placed on the pins. It is not recommended to perform any further soft tissue releases at this stage. Release may correct the deformity in extension, but create instability in flexion.

Figure 44

Figure 45
1.25 mm resection block and 2 degree varus / valgus block

At this stage, the anticipated extension gap is assessed.

Ensure that the pop-up saw capture on the distal cutting block is pushed in. The distal face now represents the level of the cut.

Fully extend the knee, and assess the gap between the distal resection block and the cut proximal tibia.

The extension gap must equal the flexion gap. If the spacer block is parallel and aligns with the tibial cut while medial and lateral tissues are equally tensioned, the distal cutting block is correctly located. The distal cutting block can be positioned using a different row of holes (2.5 mm apart) to resect a greater or lesser amount of distal femur to ensure the spacer block will fit in the extension gap (Figure 46).

Ensure that the pop-up saw capture on the distal cutting block is open. Conduct a final check of the distal resection level with the visualisation wing. The distal femoral resection is performed through the cutting slot at 15 degrees using a 1.47 mm saw blade (Figure 47). Extend the knee and insert the spacer block (with the tibial shim if it was used for the flexion gap) to check the extension gap created by the distal femoral cut (Figure 48). If required the distal resection can be retaken by moving the 2.5 mm cutting block back one row of pins, or by using either a 1.25 mm resection block or varus / valgus 2 degree recut block. Remove pins after the final distal resection has been made.
Final Femoral Preparation

The appropriate sized femoral 4-in-1 cutting block is selected and positioned on the resected anterior and distal surfaces of the femur. The fixation pin hole bosses on each side of the block correspond exactly to the M/L dimension of the final implant. A centreline is engraved on the block representing the mid point of the final implant.

Both can be used to visually place the instrument in the correct M/L position (Figure 49). The block is pinned in place through the fixation pinholes with at least two pins before any bone cuts are made. Ensure the cutting block sits flush on the anterior and distal resections. Final resections are made using a 1.47 mm saw blade in the following order:

Chamfer cuts, Sulcus cut and Peg (Lug) holes (Figures 50, 51 and 52).

**For PS final femoral preparation after chamfer cuts see Appendix C.**

**Note:** After femoral preparation and before implantation, it is essential to irrigate the surgical site to remove any potential debris.

**Alternative Femoral Cutting Block**
Select the appropriate sized femoral cutting block with feet and position on the resected anterior, posterior and distal surfaces of the femur (Figure 53). The outer edge of the posterior feet correspond exactly to the M/L dimension of the final implant. Resection is in the same order as stated previously. The posterior chip cut can be taken guided from the posterior distal edge of the block.
Tibial Preparation

Align the tibial trial to fit with the tibia for maximum coverage or, if electrocautery marks are present, use these for alignment. Pin the trial with two pins. The tray trial allows for M.B.T. keeled, M.B.T. non-keeled and M.B.T. DUOFIX implant preparation (Figure 54).

Attach the M.B.T. drill tower to the tray trial (Figure 55). Control the tibial reaming depth by inserting the reamer to the appropriate coloured line (Figure 56). An optional modular drill stop is available to provide a hard stop when reaming. See table for appropriate size.

</table>

Note: For cemented preparation, select the “Cemented” instruments, and for non-cemented or line-to-line preparation, select the “Non-Cemented” tibial instruments. The Cemented instruments will prepare for a 1 mm cement mantle around the periphery of the implant.
Keeled Tray Option
If an M.B.T keeled tray is to be employed and the bone of the medial or lateral plateau is sclerotic, it is helpful to initially prepare the keel slot with an oscillating saw or high speed burr. Assemble the M.B.T. punch impactor to the appropriately-sized M.B.T. keel punch by pressing the side button and aligning the vertical marks on both impactor and keel punch (Figure 57). Insert assembly into the M.B.T. drill tower, taking care to avoid malrotation. Impact the assembly into the cancellous bone until the shoulder of the keel punch impactor is in even contact with the M.B.T. drill tower (Figure 58).

Non-Keeled Tray Option
For a non-keeled tray option, assemble the M.B.T. punch impactor to the appropriately sized M.B.T. non-keeled punch (Figure 59) and follow the same routine as Figures 57 and 58.

Final Trialing Option
Remove the M.B.T. punch impactor from the punch by pressing the side button and remove the drill tower as well. Place the trial femoral component on the distal femur. Place the appropriate tibial insert trial onto the tray trial and repeat previous trial evaluation. A secondary and final trialing step can be performed after tibial preparation.
M.B.T. DUOFIX Tray Option
Pin the trial with 2 pins (Figure 60). Attach the M.B.T. drill tower to the tray trial (Figure 61).

Control the tibial reaming depath by inserting the DUOFIX reamer to the appropriate coloured line (Figure 62).

An optional modular drill stop is available to provide a hard stop when reaming. See table for appropriate size. For a DUOFIX Tray option, assemble the M.B.T. punch impactor to the appropriately sized M.B.T. DUOFIX punch and follow the same routine as Figures 57 and 58.

<table>

To finalise the rotational position, the four peg holes must be prepared. Attach the tray trial alignment handle and verify that orientation of the tibial trial corresponds to the markings on the tibia. Pin the tibial template, and drill the four peg holes, taking care to avoid malrotation (Figure 63).
Trialing
Remove the punch impactor from the punch by pressing the side button and remove the drill tower as well. Place the appropriate tibial insert trial onto the M.B.T. trial tray (Figure 64). The knee is placed in deep flexion.

Impact the femoral trial onto the distal femur using the femoral impactor (Figure 65).

A curved osteotome can be used to take the posterior chip cuts (Figure 66).

It is important to take the posterior chip cuts and remove any remaining osteophytes, as it may influence flexion.

Note: After tibial preparation and before implantation, it is essential to irrigate the surgical site to remove any potential debris.
Patellar Preparation

Remove the patellar wafer. The three pegs are marked for the trial patella component. The template is removed and the trial patellar component is pressed onto the resected patellar surface in the same location (Figure 67).

Reduce the patella and evaluate tracking through flexion and extension. The metal portion of the patella should remain parallel with the knee joint. Final peg holes can be drilled when all adjustments have been made (Figure 68).
Cementing Technique

Prepare the sclerotic bone to ensure a continuous cement mantle with good cement interdigitation. This can be done by drilling holes and cleansing the bone by pulsatile lavage (Figure 69). Any residual small cavity bone defects should be packed with cancellous autograft, allograft or synthetic bone substitutes such as CONDUIT™ TCP.

Note: Blood lamination can reduce the mechanical stability of the cement, therefore it is vital to choose a cement which reaches its working phase early.

Whether mixed by the SMARTMIX™ Vacuum Mixing Bowl or the SMARTMIX CEMVAC® Vacuum Mixing System, SMARTSET® GHV Bone Cement offers convenient handling characteristics for the knee cementation process.

A thick layer of cement can be placed either on the bone (Figure 70) or on the implant itself.
Tibial Implantation
Attach the M.B.T. tibial impactor by inserting the plastic cone into the implant and tighten by rotating the lock knob clockwise. Carefully insert the tibial tray avoiding malrotation (Figure 71). When fully inserted, several mallet blows may be delivered to the top of the tray inserter. If using a cemented component remove all extruded cement using a curette.

Polyethylene Implantation
Remove loose fragments or particulates from the permanent tibial tray. The appropriate permanent tibial insert can be inserted.

Femoral Implantation
Hyperflex the femur and sublux the tibia forward. Attach the slap hammer or universal handle to the femoral inserter / extractor. Position the appropriately sized femoral component on the inserter / extractor by depressing the two triggers to separate the arms and push the femoral component against the conforming polyethylene. Release the triggers so that the arms engage in the slots on the femoral component and rotate the handle clockwise to lock (Figure 72). Extend the knee to approximately 90 degrees for final impaction. Release the inserter / extractor by rotating the handle counter-clockwise and push the two triggers with thumb and index finger. For final femur impaction use the femoral notch impactor to seat the femur component. If using a cemented component clear any extruded cement using a curette (Figure 73).

Patella Implantation
Any of the LCS 3 peg patellas can now be implanted if required.
Note: Before closure it is essential to irrigate the surgical site to remove any potential debris.

Release the tourniquet and control bleeding by electrocautery. Place a closed-wound suction drain in the suprapatellar pouch and bring out through the lateral retinaculum.

Re-approximate the fat pad, quadriceps mechanism, patella tendon and medial retinaculum with interrupted sutures.

Fully rotate the knee from full extension to full flexion to confirm patellar tracking and the integrity of the capsular closing (Figure 74).

Note the final flexion against gravity for post-operative rehabilitation. Re-approximate subcutaneous tissue and close the skin with sutures or staple.
Appendix A: Tibial I.M. Jig Alignment

The entry point for the intramedullary alignment rod is a critical starting point for accurate alignment of the intramedullary alignment system.

In most cases, this point will be centred on the tibial spine in both medial / lateral and anterior / posterior aspect. In some cases, it may be slightly eccentric.

The knee is flexed maximally, the tibial retractor is inserted over the posterior cruciate ligament and the tibia is subluxed anteriorly. All soft tissue is cleared from the intercondylar area. The tibial spine is resected to the highest level of the least affected tibial condyle.

Position the correct size fixed bearing or mobile bearing tray trial on the proximal tibia to aid in establishing a drill point.

Drill a hole through the tray trial to open the tibia intramedullary canal with the I.M. 9 mm starter drill (Figure 75).

The intramedullary rod is passed down through the medullary canal until the isthmus is firmly engaged (Figure 76).
Appendix A: Tibial I.M. Jig Alignment

Remove the handle and place the I.M. rotation guide over the I.M. rod to define the correct rotational tibia axis, referring to the condylar axis, medial 1/3 of the tibia tubercle and the centre of the ankle (Figure 77). The angle can also be checked relative to the posterior condylar axis by moving the slider forward and rotating it until it is aligned with the posterior condyles. The marks on the rotation guide are in 2 degree increments and give an indication of the angle between the posterior condylar axis and the chosen rotation.

The rotation can then be marked through the slot on the rotation guide. The rotation guide can then be removed. After the correct rotation has been marked, slide the I.M. tibial jig over the I.M. rod and rotate the I.M. jig until the rotation line on the jig lines up with the line previously marked using the rotation guide. Assemble the appropriate 7 degree, left / right or symmetrical cutting block to the I.M. tibial jig in line with the marked rotation (Figure 78). Additional posterior slope can be added through the slope adjustment knob.

*Note: The number in the window indicates the amount of ADDITIONAL SLOPE that has been added.*
Appendix A: Tibial I.M. Jig Alignment

Slide the appropriate fixed or adjustable stylus in the tibial cutting block slot. When measuring from the less damaged side of the tibia plateau set the stylus to 8 mm or 10 mm. If the stylus is placed on the more damaged side of the tibia plateau, set the stylus to 0 mm or 2 mm (Figure 79).

Slide the total construct as close as possible towards the proximal tibia and lock this position. Adjust the correct degree of slope by rotating the slope adjustment screw.

The correct block height can be obtained by unlocking the distal proximal lock and lowering the bottom half of the block until the stylus is resting on the desired part of the tibia. Lock the device, by turning the distal proximal locking screw, when the correct position has been reached.

After the height has been set, insert two pins through the 0 mm set of holes in the block (the stylus may need to be removed for access). The block can be securely fixed with one extra convergent pin.

+2 and –2 mm pinholes are available on the cutting blocks to further adjust the resection level where needed.

Check the position of the resection block with an external alignment guide before making any cut. Unlock the intramedullary alignment device from the cutting block and remove the I.M. rod.
Appendix B: Spiked Uprod

Assemble the appropriate 7 degree, left / right or symmetrical cutting block to the spiked uprod (Figure 80). Slide the spiked uprod into the ankle clamp assembly.

Place the knee in 90 degrees of flexion with the tibia translated anteriorly and stabilised. Place the ankle clamp proximal to the malleoli and insert the larger of the two proximal spikes in the centre of the tibial eminence to stabilise the EM alignment device. Loosen the A/P adjustment lock and position the cutting block roughly against the proximal tibia and lock the knob. Position the cutting block at a rough level of resection and tighten the distal proximal lock (Figure 81).

Varus / Valgus

Establish rotational alignment by aligning the tibial jig ankle clamp parallel to the transmalleolar axis. The midline of the tibia is approximately 3 mm medial to the transaxial midline.

Translate the lower assembly medially (usually to the second vertical mark) by pushing the varus / valgus adjustment wings.

There are vertical scribe marks for reference aligning to the middle of the talus.

Figure 80

Figure 81
### Appendix B: Spiked Uprod

#### Slope

The spiked uprod and ankle clamp are designed to prevent an adverse anterior slope. On an average size tibia this guide will give approximately a 7 degree tibial slope when the slope adjustment is translated posteriorly until it hits the stop. In some cases a slight amount of slope will remain (1-2 degrees).

The angle of the tibial slope can be increased to greater than 7 degrees should the patient have a greater natural slope (Figure 82). First unlock the slide locking position and then translate the tibial slope adjuster anteriorly until the desired angle is reached.

As each patient’s anatomy varies, the spiked uprod can be used for both smaller and larger patients. The length of the tibia influences the amount of slope when translating the adapter anteriorly. The 7 degree default position can be overridden by pressing the slope override button and moving the slope adjustment closer to the ankle (Figure 82).

On the spiked uprod 5, 6 and 7 zones are present, which correspond to the length of the tibia. These markings can be used to fine tune the amount of slope.

When the spiked uprod shows a zone marked “7”, this indicates that when the lower assembly is translated 7 mm anterior, it will give an additional 1 degree of posterior slope (Figure 83).
Appendix B: Spiked Uprod

Tibial Resection
After the height has been set, tighten the distal proximal lock and pin the block through the 0 mm set of holes (the stylus may need to be removed for access).

+2 and -2 mm pinholes are available on the resection blocks to further adjust the resection level where needed. The block can be securely fixed with one extra convergent pin (Figure 84).

Spiked Uprod Removal
1. Loosen the distal proximal lock.

2. Connect the slap-hammer to the top of the spiked uprod and disengage the spikes from the proximal tibia.

3. Press the cutting block release button to disengage from the cutting block.

Remove the tibial jig and perform the appropriate resection (Figure 85).
Appendix C: PS Final Femoral Preparation

Femoral Sulcus and PS Box Cut
Select the appropriate size of femoral PS notch guide and position on the resected anterior and distal surfaces of the femur (Figure 86).

Ensure the notch guide sits flush on the resected femur.

The M/L edges on each side of the block correspond exactly to the M/L dimension of the final implant (Figure 86).

*Note: This M/L position should be checked before final positional cuts and lug holes are made.*

Make final resections using a 1.47 mm saw blade in the following order:

- Notch cuts (Figures 87 and 88)
- Sulcus cut (Figure 89)
- Peg (Lug) holes (Figure 90).

*Note: Take care to ensure the saw blade remains within the box cut window and does not stray into the condyles.*

*Note: After femoral preparation and before implantation, it is essential to irrigate the surgical site to remove any potential debris.*
