TomoFix Medial Distal Femur (MDF).
For closed-wedge varus distal femoral osteotomies.

Features and Benefits

<table>
<thead>
<tr>
<th>Reduced prominence</th>
<th>Anatomical fit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chamfer at the distal plate end</td>
<td>Twisted neck (stem in relation to head)</td>
</tr>
</tbody>
</table>

Improved screw direction
Curved plate positions screws centrally through the medullary canal
Easy submuscular plate insertion
Slimmer stem design with centered holes and tapered end

Reduced prominence
Shorter plate design due to pure locking holes

TomoFix Knee Osteotomy System

TomoFix Tibial Head Plate medial, proximal
- For open and closed-wedge high tibial osteotomies
- Increased plate strength allows application of the preload technique
- Facilitates the support for stable bridging
- Available in standard and small stature versions

TomoFix Tibial Head Plate lateral, proximal
- For open and closed-wedge osteotomies
- Fixed-angle construct for stable fixation
- Available in right and left versions

TomoFix Femoral Plate medial, distal
- For closed-wedge osteotomies
- Fixed-angle construct for stable fixation
- Available in right and left versions

TomoFix Femoral Plate lateral, distal
- For open and closed-wedge osteotomies
- Fixed-angle construct for stable fixation
- Available in right and left versions
Additional Notes (read carefully before proceeding)

- **When manifest instability of the lateral bony bridge is identified intraoperatively, the use of an additional lateral implant is highly recommended.**
- An exact preoperative plan is crucial to the success of this procedure. It must be done on the weight bearing x-ray of the full leg in AP view, either on paper or at a digital workstation.
- If the osteotomy wedge removed is too large, this may result in instability of the construct.
- Direction and localization of the osteotomy are important for primary stability. To achieve a high level of stability, make sure that the transverse osteotomy
  - is **isosceles** ($L_1 = L_2$). This ensures full cortical contact after closing the osteotomy.
  - is **oblique**. This maximizes the contact surface.
  - runs from the **medial metaphyseal area into the lateral condyle** as blood supply and biomechanical circumstances are most suitable in this area.
- Always use sharp saw blades as the use of a blunt saw blade may lead to thermal necrosis of the bone and the surrounding soft tissue.

- **Note on biplanar osteotomy technique**¹,²:
The AO Knee Expert Group advises to use a biplanar osteotomy technique for closed-wedge varus osteotomies of the medial distal femur. In this technique two incomplete sawcuts in the frontal plane are combined with a sawcut in the sagittal plane to improve intraoperative stability, postoperative functional rehabilitation and shorten bone healing time and time to full weight bearing.

**Alternative**³,⁴:
The closed wedge varus femur osteotomy may also be performed as a single plane osteotomy fixed with the Tomofix MDF plate.
AO Principles

In 1958, the AO formulated four basic principles, which have become the guidelines for internal fixation¹,².

Anatomic reduction
Fracture reduction and fixation to restore anatomical relationships.

Early, active mobilization
Early and safe mobilization and rehabilitation of the injured part and the patient as a whole.

Stable fixation
Fracture fixation providing absolute or relative stability, as required by the patient, the injury, and the personality of the fracture.

Preservation of blood supply
Preservation of the blood supply to soft tissues and bone by gentle reduction techniques and careful handling.

Indications and Contraindications

**Indications**
Closed-wedge osteotomies of the medial distal femur for the treatment of:
- Unicompartmental lateral gonarthrosis with valgus malalignment of the distal femur
- Idiopathic or posttraumatic valgus deformity of the distal femur
- Additional fixation for complex distal femoral fractures

**Contraindication**
- Inflammatory arthritis

**Note:** When manifest instability of the lateral bony bridge is identified intraoperatively, the use of an additional lateral implant is highly recommended.
### 1. Prepare the implant

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>03.120.068</td>
<td>TomoFix Guiding Block, for right TomoFix Femoral Plate, medial, distal</td>
</tr>
<tr>
<td>or</td>
<td>TomoFix Guiding Block, for left TomoFix Femoral Plate, medial, distal</td>
</tr>
<tr>
<td>323.042</td>
<td>LCP Drill Sleeve 5.0, for Drill Bits Ø 4.3 mm</td>
</tr>
</tbody>
</table>

To allow uniform orientation the four combination holes in the proximal stem are numbered 1–4 and the four plate holes in the distal segment are labeled A–D. Ensure that the correct implant (right/left) is selected.

Use the guiding block as a positioning guide to align the drill sleeves on the distal part of the TomoFix Femoral Plate (MDF).

Insert the drill sleeves exactly along the guiding block. First screw the drill sleeve into hole A, then proceed to screw the drill sleeves into the three remaining holes B–D.

Remove the guiding block.
2. Position the patient

Surgery is performed with the patient in a supine position. Position the patient so that the hip, knee and ankle joint can be visualized with the image intensifier. Lower the contralateral leg at the hip joint to facilitate access to the medial distal femur. The sterile draping also exposes the iliac crest so that the leg axis can be checked intraoperatively. A sterile tourniquet can be used, but is not mandatory.
3. Approach

With the knee joint in extension, make an anteromedial longitudinal incision, starting 10 cm above the patella and ending in the upper third of the patella. This incision has the advantage that it can be used again for any subsequent surgery (i.e. endoprosthesis).

Incise the subcutaneous tissue and dissect the fascia from the vastus medialis muscle. Elevate the muscle from the intermuscular septum and dissect as far as necessary for plate positioning on the femur shaft.

Position a retractor on the lateral side, over the soft tissues covering the ventral part of the femur. In the bipolar osteotomy technique visualization of the ventral part of the femur is not necessary. Incise the distal insertion of the vastus medialis muscle in order to facilitate mobilization of the muscle. Now expose the intermuscular septum near the condyles. Incise the periosteum just ventral to the septum. Use a curved elevator to separate the soft tissue from the back of the distal femur so that a wide, blunt-tipped Hohmann retractor can be inserted behind the femoral shaft.

Precaution: An osteotomy of the distal femur may be carried out only if the neurovascular structures are protected with a blunt retractor. Otherwise there is a high risk of injuring these vital structures.

Use a Hohmann retractor to expose the anteromedial aspect of the supracondylar region of the femur leaving the soft tissue covering the bone intact. Expose the femoral shaft proximally so that the TomoFix Femoral Plate (MDF) can be positioned safely.

If the plate is used for fracture fixation proceed on page 14 “Positioning and Fixation of the Plate”.
1. Determine the position of the osteotomy

Instrument

| 292.210 | Kirschner Wire Ø 2.0 mm with trocar tip, length 280 mm, Stainless Steel |

The position of the osteotomy is best determined by placing the TomoFix Femoral Plate (MDF) directly on the anteromedial distal femur. It is not necessary to achieve a form fit due to the angular stability. However, it is important to ensure that the distal screws do not penetrate the condyles dorsally.

Plan a biplanar osteotomy with the transverse plane perpendicular to the dorsal and the medial cortex. The transverse osteotomy cuts should pass through ¾ of the bone leaving the ventral ¼ intact, and end 5–10 mm before the lateral cortical bone, leaving a lateral hinge. The coronal cut must ascend anteriorly at 90°–110° and should exit the anterior cortex after 2–5 cm. The transverse osteotomy should be located under the solid region of the plate to allow screws A–D to be positioned distal of the osteotomy.

Precaution: Direction and localization of the osteotomy are important for primary stability. To achieve a high level of stability, make sure that the transverse osteotomy
• is isosceles (L1 = L2). This ensures full cortical contact after closing the osteotomy.
• is oblique. This maximizes the contact surface.
• runs from the medial metaphyseal area into the lateral condyle as blood supply and biomechanical circumstances are most suitable in this area.
Using the image intensifier, choose the hinge point of the osteotomy just proximal to the upper margin of the lateral femur condyle 5–10 mm from the lateral cortex. Insert two Kirschner wires aimed to coincide at the hinge point. The distance between the Kirschner wires at the entry point is according to the preoperative planning which is checked using a ruler. Insert two other Kirschner wires parallel to the first ones.

The resulting wedge should be isosceles in order to ensure that the medial cortices will align after the osteotomy is closed.

**Note:** In order to monitor the rotation when closing the osteotomy after removing the wedge mark the bone proximal and distal of the osteotomy with electrocautery or Kirschner wires.
2. Osteotomy

**Instruments**

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>519.114</td>
<td>Saw Blade 116/95 × 19×21.25/1.13 mm for Oscillating Saw with AO/ASIF Coupling</td>
</tr>
<tr>
<td>519.106</td>
<td>Saw Blade 90/69 × 1 × 1.0/0.8 mm, for Oscillating Saw with AO/ASIF Coupling</td>
</tr>
</tbody>
</table>

Perform the transverse osteotomy cuts in the dorsal 3/4 of the bone parallel to the inserted Kirschner wires. The wires will then act as a guide for the saw. Perform the osteotomies with an oscillating saw, protecting the soft tissues dorsally with a Hohmann retractor and constantly cooling the saw blade.

Perform the ascending osteotomy cut in the ventral ¼ of the bone with a thinner saw blade protecting the soft tissue with the Langenbeck soft tissue retractor and constantly cooling the saw blade.

Remove the wedge and check that any residual bone fragments have been removed from the osteotomy before closing. If the bone is very hard, weaken the lateral cortical bone with a 2.5 mm drill bit or Kirschner wire.

**Precaution:** Proceed cautiously around the neurovascular structures. Saw in a slow and controlled manner to prevent the blade from deviating into the back of the knee. Ensure the retractor always follows the osteotomy lines while cutting. In order to avoid potential heat necrosis during sawing procedure:

* Continuously irrigate while sawing
* Never use a blunt saw blade
3. Close osteotomy

<table>
<thead>
<tr>
<th>Instruments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>03.108.030</td>
<td>Alignment Rod</td>
</tr>
<tr>
<td>03.108.031</td>
<td>Stand, large, for Alignment Rod, with handles</td>
</tr>
<tr>
<td>03.108.032</td>
<td>Stand, small, for Alignment Rod</td>
</tr>
</tbody>
</table>

Close the osteotomy carefully by applying continuous pressure to the lateral lower limb while stabilizing the knee joint region. This may take several minutes.

The osteotomy gap can then either be held closed by manual compression or with two crossed Kirschner wires, considering the later plate position.

Check the corrected mechanical axis with the image intensifier. Position the alignment rod between the center of the femoral head and the center of the ankle joint. The projected axis line passes either centrally or medially through the center of the knee joint, depending on the preoperative planning.
1. Position the implant

**Instruments**

<table>
<thead>
<tr>
<th>Code</th>

</tr>
<tr>
<td>292.210</td>
<td>Kirschner Wire 2.0 mm with trocar tip, length 280 mm, Stainless Steel</td>
</tr>
</tbody>
</table>

Position the TomoFix Femoral Plate (MDF) anteromedially on the distal femur.

**Precaution:** Use the four distal pre-mounted drill sleeves as described on page 7, so that the solid plate segment bridges the osteotomy and the implant stem is aligned parallel to the femoral shaft.

Temporarily secure the plate through the drill sleeve.

**Precaution:** Use a centering sleeve and a Kirschner Wire in plate hole A.
Precaution: Check plate position and trajectory of the Kirschner wire under the image intensifier. The Kirschner wire must not exit the condyles posteriorly. Check by palpation and if necessary modify the plate position or sagittal tilt.

A second Kirschner wire may be inserted in plate hole 3 to maintain the alignment of the plate relative to the femur shaft during distal plate fixation.
2. Distal fixation of the TomoFix Femoral Plate

**Positioning and Fixation of the Plate**

### Instruments

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>

</tr>
<tr>
<td>314.150</td>
<td>Screwdriver Shaft, hexagonal, large, Ø 3.5 mm</td>
</tr>
</tbody>
</table>

Drill screw holes.

**Precaution:** Use the drill sleeves for self-tapping locking screws and the LCP drill bit Ø 4.3 mm.

Determine the screw length either by reading the drilled depth from the laser mark on the drill bit or with the depth gauge after removing the drill sleeve. The selected screws should be as long as possible without protruding through the lateral cortical bone.

Insert the screws using a power tool, but do not fully tighten. Insert screws in holes B, C and D. Remove the Kirschner wire from hole A and replace it with a locking screw. Using the image intensifier, exert special care to ensure that the screws do not penetrate the intercondylar notch.

Finally, lock the screws manually using the torque limiter. After one click, the optimum torque is reached.

If the plate is used for fracture fixation proceed on page 19 “Proximal fixation of the TomoFix Femoral Plate”.
3. Temporary compression of the osteotomy gap

Instruments

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>323.500</td>
<td>LCP Universal Drill Guide 4.5/5.0</td>
</tr>

</tr>
</tbody>
</table>

The osteotomy gap can be compressed by eccentrically applying a self-tapping 4.5 mm cortex screw proximal to the osteotomy in the dynamic part of combination hole 1.

The screw should be inserted perpendicular to the plate surface to achieve good interfragmentary compression. This is particularly important if the lateral femoral cortical bone fractured during closure of the osteotomy.
**Alternative instrument**

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>321.120</td>
<td>Tension Device, articulated, span 20 mm</td>
</tr>
</tbody>
</table>

Alternatively, the articulated tension device can be used to create compression in the dynamic section of plate hole 4. This requires additional proximal soft tissue dissection.
4. Proximal fixation of the TomoFix Femoral Plate

<table>
<thead>
<tr>
<th>Instruments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>323.500</td>
<td>LCP Universal Drill Guide 4.5/5.0</td>
</tr>
<tr>
<td>315.310</td>
<td>Drill Bit $\odot$ 3.2 mm, length 145/120 mm, 3-flute, for Quick Coupling</td>
</tr>
<tr>
<td>397.705</td>
<td>Handle for Torque Limiter Nos. 511.770 and 511.771</td>
</tr>
<tr>
<td>511.771</td>
<td>Torque Limiter, 4 Nm, for Compact Air Drive and Power Drive</td>
</tr>
<tr>
<td>314.150</td>
<td>Screwdriver Shaft, hexagonal, large, $\odot$ 3.5 mm</td>
</tr>
</tbody>
</table>

Use an LCP universal drill guide to mark the medial femoral cortical bone with the short drill bit. Screw in the locking screw using a power tool and tighten it using the technique described on page 16.
Insert monocortical, self-tapping locking screws into plate holes 2–4 of the implant stem from distal to proximal.

**Note:** In cases requiring increased stability such as compromised bone quality or obese patients, the use of bicortical screws may be indicated.
5. Replace the cortex screw

**Instruments**

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>323.042</td>
<td>LCP Drill Sleeve 5.0, for Drill Bits Ø 4.3 mm</td>
</tr>
<tr>
<td>310.430</td>
<td>LCP Drill Bit Ø 4.3 mm with Stop, length 221 mm, 2 flute, for Quick Coupling</td>
</tr>
<tr>
<td>319.100</td>
<td>Depth Gauge for Screws Ø 4.5 to 6.5 mm, measuring range up to 110 mm</td>
</tr>
<tr>
<td>397.705</td>
<td>Handle for Torque Limiter Nos. 511.770 and 511.771</td>
</tr>
<tr>
<td>511.771</td>
<td>Torque Limiter, 4 Nm, for Compact Air Drive and Power Drive</td>
</tr>
<tr>
<td>314.150</td>
<td>Screwdriver Shaft, hexagonal, large, Ø 3.5 mm</td>
</tr>
</tbody>
</table>

Remove the cortex screw from hole 1 and replace it with a bicortical, self-tapping locking screw. Screw the drill sleeve exactly into the threaded part of the combi-hole and drill the hole with the LCP drill bit Ø 4.3 mm. Determine the screw length and insert the screw as described on page 16.

**Note:** In the event of a rotational osteotomy or breakage of the lateral hinge, the surgeon should consider adding a lateral implant.
6. Radiological control

Check the result of the correction and the position of the implant using the image intensifier.

7. Wound closure

Re-insert the partially released distal insertion of the vastus medialis muscle on the patella. Close the wound in layers.
Postoperative Treatment

Normal rehabilitation protocol
Early functional postoperative treatment from the first postoperative day, partial load weight bearing of 15–20 kg for 6 weeks postoperatively, manual lymphatic drainage, cryotherapy and electrotherapy if necessary. The range of motion is not limited, an orthosis is not necessary, abduction and adduction against resistance and torsion in the lower leg should be avoided for the first 6 weeks. Increased weight bearing is allowed from the 7th week postoperatively depending on the radiological healing of the osteotomy site.

Early full weight bearing protocol
Immediate full weight bearing upon pain may be considered in patients that can be trusted to be compliant to instructions. To limit torsion forces over the osteotomy during immediate full weight bearing a hinged knee brace is advised during the first 6 weeks.\(^5\)

Radiographic control after 2 days, 6 and 12 weeks and 12 months.

Note: The described rehabilitation protocols are examples only. They must be individually assessed for each patient.
Implant Removal

Generally, the TomoFix Femoral Plate (MDF) should not be removed earlier than 12 months after surgery. To remove the plate, first loosen all screws manually and then remove them using power tools.
The TomoFix Femoral Plate (MDF) is designed according to the principles of the Locking Compression Plate (LCP). In the distal section there are 4 threaded holes, the directions of which are adapted to the anatomy of the supracondylar femur. There are 2 combi-holes and 2 locking holes in the proximal section. Right and left versions allow for accurate positioning of the anteromedial section of the distal femur and secure anchorage of the locking screws in the femoral condyles.

04.120.550  TomoFix Femoral Plate, medial, distal, right, 4 holes, Pure Titanium, sterile

For closed-wedge osteotomies of the right medial distal femur

04.120.551  TomoFix Femoral Plate, medial, distal, left, 4 holes, Pure Titanium, sterile

For closed-wedge osteotomies of the left medial distal femur

413.314– 413.390  Locking Screws Ø 5.0 mm, self-tapping, Titanium Alloy (TAN)

413.426  Locking Screw Ø 5.0 mm, self-drilling, length 26 mm, Titanium Alloy (TAN)

**MRI Information**

---

**Torque, Displacement and Image Artifacts according to ASTM F 2213-06, ASTM F 2052-14 and ASTM F 2119-07**

Non-clinical testing of worst case scenario in a 3 T MRI system did not reveal any relevant torque or displacement of the construct for an experimentally measured local spatial gradient of the magnetic field of 3.69 T/m. The largest image artifact extended approximately 169 mm from the construct when scanned using the Gradient Echo (GE). Testing was conducted on a 3 T MRI system.

**Radio-Frequency-(RF)-induced heating according to ASTM F 2182-11a**

Non-clinical electromagnetic and thermal testing of worst case scenario lead to peak temperature rise of 9.5 °C with an average temperature rise of 6.6 °C (1.5 T) and a peak temperature rise of 5.9 °C (3 T) under MRI Conditions using RF Coils (whole body averaged specific absorption rate [SAR] of 2 W/kg for 6 minutes [1.5 T] and for 15 minutes [3 T]).

**Precautions:** The above mentioned test relies on non-clinical testing. The actual temperature rise in the patient will depend on a variety of factors beyond the SAR and time of RF application. Thus, it is recommended to pay particular attention to the following points:

- It is recommended to thoroughly monitor patients undergoing MR scanning for perceived temperature and/or pain sensations.
- Patients with impaired thermoregulation or temperature sensation should be excluded from MR scanning procedures.
- Generally, it is recommended to use a MR system with low field strength in the presence of conductive implants. The employed specific absorption rate (SAR) should be reduced as far as possible.
- Using the ventilation system may further contribute to reduce temperature increase in the body.
