Warning
This description alone does not provide sufficient background for direct use of the instrument set. Instruction by a surgeon experienced in handling these instruments and the attendance of a VBS training in order to know the VBS instrumentation and technique is highly recommended.

VBS Technique Guide Synthes 1

VBS is a safe treatment method for painful vertebral body fractures and lesions. It helps to prevent effects such as postural damage and pain caused by postural kyphosis.

VBS offers unique benefits to patients and physicians:

Percutaneous
The VBS stents are introduced percutaneously into the vertebral body with only a stab incision required to place the access instruments.

Reconstructive
The VBS system restores the loss of height in the fractured vertebral body.

Height conserving
Expanding the VBS stents inside the collapsed vertebra offers height restoration and conservation. The mechanical construct restores the height while at the same time offering a cavity for injection of highly viscous PMMA based bone cement cleared for use in vertebroplasty or kyphoplasty procedures.

Minimally invasive, percutaneous insertion of the Vertebral Body Stenting System
Instrument insertion through a stab incision allows performing the procedure under either local or general anaesthesia.

Vertebral Body Balloon (VBB)
Simulate stent expansion in the vertebral body prior to VBS insertion.
Restoration through balloon dilatation and stent expansion
Simultaneous dilatation of the bilaterally positioned VBS Stents offers an in situ controlled and continuous expansion.

Optional Vertebral Body Balloon pre-cavity creation
Simulation of stent expansion via balloon trialing allows fracture/lesion mobility confirmation.

Augmentation with Vertecem V+
Vertecem V+ is a PMMA based bone cement for the treatment of vertebral compression fractures:
- About 27 minutes of working time
- Excellent X-ray visibility

Expansion ratio up to 400%
The Vertebral Body Stenting technology offers an expansion ratio up to 400% for the reconstruction of collapsed vertebrae.

Controlled balloon dilatation with the VBS Inflation System
The applied pressure and injected volume of the mixture of saline solution and contrast medium can constantly be monitored and controlled with the help of the phosphorescent display.
In 1958, the AO formulated four basic principles, which have become the guidelines for internal fixation. They are:

- Anatomic reduction
- Stable fixation
- Preservation of blood supply
- Early, active mobilization

The fundamental aims of fracture treatment in the limbs and fusion of the spine are the same. But a specific goal of spine treatment is to restore as much function as possible to the injured neural elements.

**AO Principles as applied to the spine**

**Anatomic reduction**

Restoration of normal spine alignment improves the biomechanics of the spine and reduces pain by reestablishing and maintaining the natural curvature and the protective function of the spine.

**Stable fixation**

In the spine, the goal of internal fixation is to maintain not only the integrity of a mobile segment, but also to maintain the balance and the physiologic three-dimensional form of the spine. A stable spinal segment allows bony fusion at the junction of the lamina and pedicle.

**Preservation of blood supply**

The proper atraumatic technique enables minimal retraction or disturbance of the nerve roots and dura, and maintains the stability of the facet joints. The ideal surgical technique and implant design minimize damage to anatomical structures, i.e. facet capsules and soft tissue attachment remain intact, and create a physiological environment that facilitates healing.

**Early, active mobilization**

The ability to restore normal spinal anatomy may permit the immediate reduction of pain, resulting in a more active, functional patient. The reduction in pain and improved function can result when a stable spine is achieved.

---

Indications and Contraindications

**Intended use**
The VBS System is intended for the reduction of painful vertebral compression fractures and/or creation of a void in cancellous bone in the spine for the treatment of levels ranging from Th5-L5. It is intended to be used in combination with a legally-marketed PMMA \(^1\) based bone cement adequately indicated for use in vertebroplasty or kyphoplasty procedures.

**Note:** Refer to the manufacturer’s directions accompanying the bone cement for specific information on its use, precautions and warnings.

**Indications**
- Painful osteoporotic vertebral compression fractures without posterior wall involvement. Classified after Genant, Grade 2 and Grade 3.
- Painful vertebral compression fractures classified after the AO classification:
  - A1.1 Endplate impaction
  - A1.2 Wedge impaction fracture
  - A1.3 Vertebral body collapse
  - A3.1 Incomplete burst fracture; matter of discretion (depending on the degree of posterior wall involvement, internal fixation must be used in addition)
  - In combination with internal fixation:
    - A3.1 Incomplete burst fracture
    - A3.2 Burst-split fracture; matter of discretion (the extent of the gap width should not be too wide)
  - B1.2 Posterior disruption predominantly ligamentous associated with type A fracture of the vertebral body
  - B2.3 Posterior disruption predominantly osseous with type A fracture of the vertebral body
- Palliative treatment of osteolytic lesions located within the vertebral body with intact cortical shell. Classified after Tomita Type 1.

**Contraindications**
- Lesions requiring open anterior column reconstruction
- Acute or chronic systemic or localized spinal infections

\(^1\)\text{Note: The long-term effects of PMMA based cements on the vertebral column are unknown. Therefore, the treating physician should weigh the benefits of the application of the PMMA based cement in younger patients against the potential risks.}
Preoperative Planning

**Patient assessment**
Requirements for assessing the indication:
- Current X-ray images, if possible in standing position, of the thoracic and lumbar spine in two planes to assess the fracture and spinal alignment
- A spiral CT and MRI scan (ideally with STIR frequency) of the painful region of the spine
- If an MRI scan is contraindicated a bone scan may identify an acute fracture
- Ruling out another cause of pain
- Feasibility of surgery and use of anaesthesia
- Ruling out impaired clotting

**Note:** It is important, to treat only patients with non-consolidated fractures.

**Warning:** The patient should be checked for allergy to the contrast medium and stent material (CoCrWNi alloy).

**Planning of stent placement**
The placement of the stents should be planned based on the AP image which gives hints for the route of insertion.

**Pre-planning of stent size**
The stent size for the procedure can roughly be planned preoperatively via CT scan.

**Intraoperative X-ray imaging**
The Vertebral Body Stent must be implanted using X-ray on both planes, two C-arms, or with one freely mobile C-arm.
**Instrument preparation**

<td>Inflation System</td>
</tr>
</tbody>
</table>

The inflation system has an angled manometer that shows the pressure in the balloon in pounds/inch$^2$ (psi) and atmospheres (atm). The volume scale on the fluid chamber measures milliliters (ml).

It is necessary to prepare two inflation systems.

1. **Connect inflation system to connector**
   
   Attach the tube of the inflation system with the Luer connector to the supplied 3-way connector as shown. Rotate the knob on the 3-way connector to position the “off” indicator towards the lateral outlet (1).

2. **Fill inflation system**
   
   Fill the inflation system with saline solution and a liquid contrast medium.

**Note:** It is essential to fill the inflation system with saline/contrast agent mixture to ensure better visibility of the VBS balloon catheter during inflation. The ratio of contrast medium to saline solution should be about 1:2.

Prepare the contrast medium mixture in a cup and place the 3-way connector under the solution. Push forward on the white wings on the inflation system and pull back on the handle until the plunger bottoms out. With the handle pointing upwards, tap the unit to clear the gauge portion of the inflation system of air (2).
Then hold the inflation system with the handle facing downward, and rotate the handle clockwise to expel all the air in the barrel until solution starts to emerge. Keep turning the handle clockwise until the leading edge of the red mark on the plunger reaches to approximately 3 to 4 ml under the zero marking or until the red marker on the plunger is aligned with the black line above the ml sign, underneath the zero marking (3).

The inflation system has now been prepared accordingly and can be set aside. Repeat for the second inflation system.

Tip: The white wings may be pushed to unlock the plunger when large changes to the handle position are desired. The handle must be moved carefully to avoid overshooting the desired target.

Warning: If the buttons (white wings) do not return to the locked position, do not force them as this could damage the plunger. Turn the handle gently, and the buttons (white wings) will return automatically to the locked position.
Anatomical landmarks

For vertebral body augmentation with VBS, the two stents per vertebra should be placed in a symmetrical, paramedian position within the affected vertebral body to achieve optimum reduction of the spinal fracture without damaging the lateral vertebral body edges. Ideally, the distance from the compressed endplate to the stents should be about 5 mm (1).

The position of the stents needs to be planned based in pre-operative imaging. Take care to achieve the planned position by determining the landmarks accordingly.

The following landmarks have to be defined on the spine:
- Both pedicles
- Spinous process
- Endplates
- Posterior wall of vertebral body
Patient Positioning

Place the patient in the prone position on a lumbar support. The table must be radiolucent in both planes.

The OR table should allow free manipulation of the C-arm over the operative site in both planes.
Access Options

There are two access options to the targeted vertebral body, depending on its anatomy:

1. Transpedicular access
   As a general rule, the bilateral skin incisions for the transpedicular approach are 1–2 cm lateral and up to 1 cm cranial to the centre of the pedicle (1).

2. Extra-/Parapedicular access
   The bilateral skin incisions for the extra-/parapedicular technique are planned according to the anatomical situation (2).

The instruments for inserting the VBS system can be placed using either a guide wire or a trocar. In the chapter “Instrument Positioning” each procedure is explained for a transpedicular and an extra-/parapedicular access.

For positioning instruments with guide wires see page 13.
For positioning instruments with trocar see page 20.
Instrument Positioning
A With Guide Wires

Instrument Set

03.804.512S Vertebral Body Stent Access Kit

First the guide wires are positioned. The other instrumentation follows the path created by the guide wires.

Once the anatomical landmarks are detected, the guide wires can be percutaneously introduced through skin incisions using X-ray control (AP and lateral).

Either a transpedicular or extra-/parapedicular access may be selected depending on the anatomy of the vertebral body to be treated.

Note: With either access technique it is important to plan to place the two stents symmetrically towards the midline and the anterior wall of the vertebral body at a medial location. In this position the stents have room to expand without pressing against either the lateral wall, or the other stent (1).
1

Position guide wires

Make the skin incisions.

Under AP and lateral X-ray control insert the guide wires to the superior outer pedicle quadrant using slight manual pressure.

Once the guide wires touch bone the outlines of the lateral pedicle are reached. Drive both guide wires with controlled blows from a hammer through the cortex. Cautiously advance the guide wires into the center of the vertebral body.

**Note:** The tips of the guide wires should be about and not closer than 5 mm to the anterior wall of the vertebral body. They should be positioned symmetrically and aligned in both AP and lateral views. Confirm this placement for the positioning of the stents.

**Warning:** The tips of the guide wires must not pass the midline in AP view until they have passed the posterior wall in the lateral view. When advancing the guide wires, ensure that they are not inserted too far medially, to avoid penetration into the spinal canal. It is also essential to avoid over-driving the guide wires into vascular structures beyond the anterior cortical wall.
2 Position working sleeves over guide wires

Take the instrument assembly of working sleeve, side-opening cannula and cannulated trocar (1). Push the instrument assembly with a counterclockwise turning motion over the first guide wire (2).

**Warning:** Do not insert the working sleeve into the bone without the side-opening cannula. This could damage the working sleeve and obstruct stent insertion. Do not hammer on the side-opening cannula, cannulated trocar and working sleeve.

The working sleeve can also be placed without the mounted cannulated trocar (working sleeve with side-opening cannula over guide wire). If this method is chosen, there is more clearance between the diameter of the guide wire and the side-opening cannula to allow for minor correction in the trajectory when positioning the working sleeve. This can lead to a slight resistance when penetrating the bony vertebral body surface.
Monitor working sleeve placement under lateral X-ray control. Ensure that the tip of the working sleeve has passed the pedicle and is positioned inside the vertebral body.

**Note:** When inserting the working sleeve, carefully monitor the position of the guide wire to confirm that it is not advancing forward.

**Tip:** Pull back the side-opening cannula to verify the positioning of the working sleeve.

**Repeat on the contra-lateral side (4).**

Once both working sleeves are in place, remove the side-opening cannulae with the inserted cannulated trocar and the guide wires (5).

The working sleeves remain in the vertebral body.

**Warning:** It is important to advance the instrument assembly carefully in order to avoid any injury to the physician’s hand. Since the guide wire is longer than the combined length of the pre-mounted working sleeve with the side-opening cannula with cannulated trocar, it will protrude through the handle of the side-opening cannula (6).
1

**Position guide wires**

Make the skin incisions.

- Under AP and lateral X-ray control, insert the guide wires using slight manual pressure.

Insert both guide wires up to the vertebral body and drive them with controlled blows from a hammer through the cortex. Should you touch bone before reaching the vertebral body you have reached the outline of the lateral pedicle.

**Note:** Cautiously advance the guide wires and, if necessary, redirect in order to reach the center of the vertebral body. The tips of the guide wires should be about and not closer than 5 mm to the anterior wall of the vertebral body.

**Warning:** The tips of the guide wires must not pass the midline in AP view until they have passed the posterior wall in the lateral view. When advancing the guide wires, ensure that they are not inserted too far medially, to avoid penetration into the spinal canal. It is also essential to avoid overdri
ing the guide wires into vascular structures beyond the anterior cortical wall.
2

Positioning working sleeves over guide wires

Take the instrument assembly of working sleeve, side-opening cannula and cannulated trocar (1). Push the instrument assembly with a counterclockwise turning motion over the first guide wire (2).

**Warning:** Do not insert the working sleeve into the bone without the side-opening cannula. This could damage the working sleeve and obstruct stent insertion. Do not hammer on the side-opening cannula, cannulated trocar and working sleeve.

The working sleeve can also be placed without the mounted cannulated trocar (working sleeve with side-opening cannula over guide wire). Then, there is more clearance between the diameter of the guide wire and the side-opening cannula to allow for minor correction in the trajectory when positioning the working sleeve. This can lead to a slight resistance when penetrating the bony vertebral body surface (3).
Monitor working sleeve placement under lateral X-ray control. Advance the tip of the working sleeve until it has penetrated the cortex and is tightly seated into the bone.

**Note:** When inserting the working sleeve, carefully monitor the position of the guide wire to confirm that it is not advancing forward.

**Tip:** Pull back the side-opening cannula to verify the positioning of the working sleeve.

**Repeat on the contra-lateral side (4).**

Once both working sleeves are in place, remove the side-opening cannulae with the inserted cannulated trocar and the guide wires (5).

The working sleeves remain in the vertebral body.

**Warning:** It is important to advance the instrument assembly carefully in order to avoid any injury to the physician’s hand. The guide wire is longer than the combined length of the instrument assembly of working sleeve and the side-opening cannula and cannulated trocar will protrude through the handle of the side-opening cannula (6).
Instrument Positioning
B With Trocars

Instrument Set

| 03.804.512S | Vertebral Body Stent Access Kit |

When using trocars for instrument positioning, creating the pathway and positioning of the instrumentation is achieved in one step.

Either a transpedicular or extra-/parapedicular access may be selected depending on the anatomy of the vertebral body to be treated.

**Note:** With either access technique it is important to plan to place the two stents symmetrically towards the midline.
Positioning working sleeves

Make skin incisions.

Take the instrument assembly of working sleeve, side-opening cannula and cannulated trocar. Replace the cannulated trocar by the trocar and lock it into place with a clockwise rotation (1).

Under AP and lateral X-ray control insert the instrument assembly through the skin incision to the superior outer pedicle quadrant using slight manual pressure and a counterclockwise turning motion (2). If necessary the instrument assembly can be inserted through the cortex with light impaction on the metal end of the trocar using a hammer.

Tip: Pull back the side-opening cannula to verify the positioning of the working sleeve.

Warning: When advancing the instrument assembly, ensure that the trocar tip is not inserted too far medially, to avoid penetration into the spinal canal. It is also essential to avoid overdriving the trocar tip into vascular structures beyond the anterior cortical wall.

Hold the working sleeve in place and carefully rotate and remove the trocar and the side-opening cannula. The working sleeve remains in the vertebral body.

Repeat for the contra-lateral side (3).

Warning: Do not insert the working sleeve into the bone without the side-opening cannula and trocar. This could damage the working sleeve and obstruct stent insertion.

Do not redirect the instrument assembly without removing it and re-accessing the pedicle.
Positioning working sleeves

Make skin incisions.

Take the instrument assembly of working sleeve, side-opening cannula and cannulated trocar. Replace the cannulated trocar by the trocar and lock it into place with a clockwise rotation (1).

Under AP and lateral X-ray control insert the instrument assembly through the skin incision into the vertebral body using slight manual pressure and a counterclockwise turning motion (2). If necessary the instrument assembly can be inserted through the cortex with light impaction on the metal end of the trocar using a hammer.

Advance the instrument assembly so that the opening of the working sleeve is anterior to the posterior wall of the vertebral body.

Tip: Pull back the side-opening cannula to verify the positioning of the working sleeve.

Warning: When advancing the instrument assembly, ensure that the trocar tip is not inserted too far medially, to avoid penetration into the spinal canal. It is also essential to avoid overdriving the trocar tip into vascular structures beyond the anterior cortical wall.

Hold the working sleeve in place and carefully rotate and remove the trocar and the side-opening cannula. The working sleeve remains in the vertebral body.

Repeat for the contra-lateral side (3).

Warning: Do not insert the working sleeve into the bone without the side-opening cannula and trocar. This could damage the working sleeve and obstruct stent insertion. Do not redirect the instrument assembly without removing it and re-accessing the bone.
Create Access Channel

**Instrument Set**

03.804.512S  Vertebral Body Stent Access Kit

Guide the drill (1) and afterwards the blunt plunger (2) through the working sleeves to create an access channel for the stents.

**Warning:** Use lateral X-ray intensification to avoid penetrating the anterior cortex of the vertebral body. It is essential to avoid overdriving these instruments into vascular structures beyond the anterior cortical wall.

**Warning:** Do not use a hammer to drive the drill forward. The drill may aggressively advance with rotation.

The plunger can be driven forward with light hammer blows. Ensure that the hammer blows hit the protruding metal pin and not the plastic handle (2).

**Warning:** While using drill or plunger, it is important to ensure that the working sleeves do not move. Do not use the drill or plunger to manipulate or correct the direction of the working sleeve.

Repeat on the contra-lateral side.
The Vertebral Body Stents and Balloons are available in three sizes:

The plunger has three grooves towards the distal tip that correspond to the three stent lengths (1).

Use lateral imaging to select the length of the stent on the basis of these grooves.

From distal tip the first groove visible:
Vertebral Body Stent Small

From distal tip the second groove visible:
Vertebral Body Stent Medium

From distal tip the third groove visible:
Vertebral Body Stent Large

Establish the stent size on both sides, they may differ.
If you do not intend to use the VBB please continue to page 34 chapter “Using the VBS”.

The VBS System can optionally be used with a Vertebral Body Balloon (VBB). The VBB allows simulating the stent expansion when bone quality, age of the fracture or the fracture / lesion mobility of the vertebral body is unknown.

1 Unpacking the VBB Catheter

Remove the VBB catheter from the sterile packaging (1).

**Note:** Slide back the white cover sleeve towards the Luer connector and attach it properly to the luer (2). This cover sleeve can be used later for stretching and folding back the VBB after catheter removal for reuse.

Do not remove the stiffening wire from the VBB catheter. The stiffening wire will be removed and the creation of the vacuum will be performed after the insertion of the VBB catheter on the patient. This is different compared to the VBS catheter insertion.

There is a white marking range on the balloon catheter shaft indicating release length, i.e. the overall length and both proximal and distal balloon shoulders segments when the white marking range is completely inserted into the working sleeve.

The VBB can be reused once within one surgery.

**Warning:** Only use the VBB of same size together with the corresponding VBS.

**Note:** The shaft marker indicates when balloon is fully inserted, use X-ray while inflating with contrast media.
2  

Insertion of the VBB

Insert the VBB catheter under lateral X-ray control.

**Note:** The full release (initial) length of the VBB is outside when the proximal end of the white marking of the catheter shaft disappears into the working sleeve.

Check the position under X-ray control and confirm the desired position under AP view (1). It is important, that the whole balloon portion is positioned completely inside the vertebra and that these inflatable segments have completely passed through the working sleeve. Make sure to position the VBB according to the anticipated VBS position.

Repeat for the contra-lateral side.

**Note:** Simultaneous dilatation of bilateral inserted VBBs is recommended for optimal performance.

**Note:** Make sure to position the VBB according to the anticipated VBS position.
3 Connecting VBB catheter to inflation system and create vacuum

**Instrument**

03.804.413S Inflation System

Remove stiffening wire prior to connecting the VBB to the inflation system and keep it.

**Note:** Stiffening wire will be used for balloon refolding (in conjunction with the cover sleeve) and reinsertion.

Connect the prepared inflation systems with the selected VBB catheters using the Luer connector (1).

**Note:** It is important to ensure that all Luer connectors are securely attached. Loose connections may result in inaccurate filling volumes and pressures.

Push the white wings on the inflation system forward to unlock the handle. Pull the handle all the way back, and release the wings to lock the handle in position. This pulls air out of the catheter, creating a vacuum inside it. The vacuum can be monitored on the display “vac” (2).

**Warning:** If the buttons (white wings) do not return to the locked position, do not force them as this could damage the plunger. Turn the handle gently, and the buttons (white wings) will return automatically to the locked position.
Close the balloon catheter with the 3-way connector by positioning the “off” indicator towards the catheter. This retains the vacuum inside the catheter (3).

Hold the inflation system with the handle facing downward and turn the handle clockwise in order to set the volume scale to zero. This is done by turning the handle until the red ring on the plunger is precisely at “0” (4).
This flushes out the excess saline solution/contrast medium mixture and air through the lateral opening of the three-way connector (5).

**Tip:** Suspend the 3-way connector over a receptacle for all steps that involve expelling excess solution. If vacuuming on the patient, use absorbent cotton to soak up any expelled excess solution.

Rotate the knob on the 3-way connector to position the “off” indicator towards the lateral side opening. This allows flow from the Inflation system into the VBB balloon catheter (6).
Inflation of VBB

1 Inflation of VBB

**Note:** Simultaneous dilatation of bilateral devices is recommended for optimal performance.

**Warning:** It is essential to use AP and lateral X-rays to track VBB expansion via the balloon contrast media solution inflation fluid.

Slowly increase pressure and volume by rotating the handles of the connected inflation systems in a clockwise direction on both sides.

Proceed slowly after each VBB balloon unfolds and starts expanding at approx. 12 atm (2). Match the expansion bilaterally by tracking the fluid volume on the syringe body with the black volume markers positioned in ml increments. When the pressure reaches and increases beyond 26 atm, continue dilatation gradually. Wait a few seconds then slowly continue until the desired VBB diameter is reached (3). The maximum stent diameter is 15 mm for VBB Small and 17 mm for both VBB Medium and VBB Large.

Stop balloon expansion when any of the following happens:
1. Desired vertebral body height or angle is reached
2. Pressure reaches 30 atm (400 PSI)
3. VBB volume reaches maximum
   – 4.0 ml for VBB Small
   – 4.5 ml for VBB Medium
   – 5.0 ml for VBB Large

**Note:** The VBB expansion pressure and volume on the inflation system have to be monitored carefully on the inflation system’s phosphorescent manometer (units: bar/atm, PSI) and syringe body with black volume markers (units: ml/cc), respectively.
**Warning:** Do not fill the balloons over their maximum volume or pressure. If this is done, they may leak.

**Warning:** VBB maximum volumes differ from VBS maximum volumes!

**Note:** In case of contrast medium leakage, pull vacuum, insert stiffening wire and remove balloon, don’t reuse balloon.

## 2

**Retrieve balloon catheters**

Slowly turn the handles of the inflation systems counterclockwise to draw the liquid out of the balloon catheter (1). Once the pressure has reached 10 atm, push the white wings forward, slowly pull the handle back all the way, and release the white wings (2). This draws and holds a vacuum in the catheter.
Aerate the VBB catheter by first positioning the "off" indicator towards the catheter (1) and second turn back towards the lateral side opening (1 inset).

Disconnect the inflation system from the VBB catheter.

**Note:** Carefully insert the stiffening wire into the VBB catheter under X-ray control.

Apply a gentle force in order to stretch the deflated balloon prior to removal of the catheter (2). Make sure not to damage the VBB catheter by pushing too hard.

Hold the working sleeves in place and pull carefully on the catheters to retrieve the balloons. Rotate the catheters if needed to ease balloon removal.

**Note:** The VBB catheter can be re-used once within one surgery. Make sure by visual inspection that the VBB catheter has not been damaged.

**Warning:** do not use a VBB catheter when a visual damage is observed, or when a leak is evident.

**Warning:** If balloon-catheter material is remaining in vertebral body after removal of the VBB do not leave it implanted. The balloon-catheter material is not implant grade material.
Note: If the VBB catheter is planned to be reused within the same surgery, cover the re-folded balloon of the VBB catheter with the white cover sleeve (3) and reinsert stiffening wire to gently straighten the balloon.
Using the VBS Catheter

Note: the fracture must be mobile in order height restoration is possible. In order to simulate stent expansion use optional VBB (s. page 25)

1 Unpacking the VBS Catheters

Remove the VBS catheter from the sterile packaging. Carefully remove the stiffening wire and put it aside for possible further use.

If preferred, the stiffening wire can also be removed after the insertion of the balloon catheter. If this method is chosen, the creation of the vacuum has to be performed after the insertion of the balloon catheter on the patient.

There is a white marking range on the balloon catheter shaft indicating the release length, i.e. the overall length including the stent and both proximal and distal balloon shoulders segments, when the white marking range is completely inserted into the working sleeve.
2 Connecting VBS catheter to inflation system and create vacuum

Instrument

03.804.413S Inflation System

Connect the prepared inflation system with the selected VBS balloon-catheters using the Luer connector (1).

Note: It is important to ensure that all Luer connectors are securely attached. Loose connections may result in inaccurate filling volumes and pressures.

Push the white wings on the inflation system forward to unlock the handle. Pull the handle all the way back, and release the wings to lock the handle in position. This pulls air out of the catheter, creating a vacuum inside it. The vacuum can be monitored on the display “vac” (2).

Warning: If the buttons (white wings) do not return to the locked position, do not force them as this could damage the plunger. Turn the handle gently, and the buttons (white wings) will return automatically to the locked position.
Close the balloon catheter with the 3-way connector by positioning the “off” indicator towards the catheter. This retains the vacuum inside the catheter (3).

Hold the inflation system with the handle facing downward and turn the handle clockwise in order to set the volume scale to zero. This is done by turning the handle until the red ring on the plunger is precisely at “0” (4).
This flushes out the excess saline solution/contrast medium mixture and air through the lateral opening of the three-way connector (5).

**Tip:** Suspend the 3-way connector over a receptacle for all steps that involve expelling excess solution. If vacuuuming on the patient, use absorbent cotton to soak up any expelled excess solution.

Rotate the knob on the 3-way connector to position the “off” indicator towards the lateral side opening. This allows flow from the inflation system into the VBS balloon catheter (6).
Deployment of Stents

1

Insert and deploy stents

Insert the balloon catheter with the attached stent under lateral X-ray control. The full release (initial) length of the balloon with stent is outside the working sleeve when the proximal end of the white marking of the catheter shaft disappears into the working sleeve. Check the position under X-ray control and confirm the desired position under AP view (1). It is important, that the whole balloon portion including the stent is positioned completely inside the vertebra and that these parts have completely passed through the working sleeve.

Repeat on the contra-lateral side.

Note: Simultaneous dilatation of bilateral devices is essential for optimal device performance. Once stent expansion has begun the stent cannot be undeployed or repositioned.

Warning: It is essential to use AP and lateral X-rays to track stent expansion and balloon shoulder inflation via the radiopacity due to the stent and the balloon contrast media solution inflation fluid, respectively.

Slowly increase pressure and volume by rotating the handles of the connected inflation system in a clockwise direction on both sides.
Proceed slowly after the stents begin expanding at approx.
12 atm (2). Match the expansion bilaterally by tracking the fluid volume on the scales. When the pressure reaches
26 atm, continue dilatation gradually. Wait a few seconds
then slowly continue until the desired stent diameter is
reached (3). The maximum stent diameter is 15 mm for VBS
Small and 17 mm for both VBS Medium and VBS Large.

Stop balloon inflation when any of the following happens:
1. Desired vertebral body height or angle is reached
2. Pressure reaches 30 atm
3. VBS volume reaches maximum
   – 4.5 ml for VBS Small
   – 5.0 ml for VBS Medium
   – 5.5 ml for VBS Large

**Note:** The VBS expansion pressure and volume on the inflation System have to be monitored carefully on the inflation system’s phosphorescent manometer (units: bar/atm, PSI)
and syringe body with black volume markers (units: ml/cc), respectively.

**Warning:** Do not inflate the balloons beyond their maximum volume or pressure. If this is done, they may leak.

**Warning:** VBS maximum volumes differ from VBB maximum volumes.

Once the expansion is stopped, record the volume of solution used indicated on the inflation system.
Retrieve balloon catheters

To maintain maximum stent expansion, gradually decrease the pressure simultaneously on both sides. Slowly turn the handles of the inflation system counter-clockwise to draw the liquid out of the balloon catheter (1). Once the pressure has reached 10 atm, push the white wings forward, slowly pull the handle back all the way, and release the white wings (2). This draws and holds a vacuum in the catheter and collapses the balloon for its removal.

Hold the working sleeves in place and pull firmly on the catheters to retrieve the balloons. Rotate the catheters if needed to ease balloon on removal. The stents remain in the vertebral body.

Verify the position of the bilaterally positioned stents under AP and lateral X-ray control.

**Tip:** If the stent expansion is inadvertently asymmetric or if a balloon leaks, the intact balloon catheter from the contra-lateral side can be reinserted in the vertebral body on the ipsi-lateral side and be repositioned in the stent and can be reused for further expansion. In that case, disconnect the inflation system from the balloon catheter, carefully insert the stiffening wire and replace the balloon catheter through the working sleeve in the vertebral body. Carefully monitor the insertion under lateral X-ray control. Stop insertion when the top end of the white range on the catheter shaft is aligned with the top of the working sleeve. Check the position under X-ray control and confirm the desired position under AP view. Ensure that the stent does not move while switching the balloon-catheter. Remove the stiffening wire and reconnect the inflation system, repeat the steps of creating a vacuum and re-inflate the balloon as described in this section.
Note: If the contrast medium/saline solution mixture leaks when the stents are expanded, it may be more difficult to remove the balloon catheters through the working sleeves. If necessary remove the balloon catheters together with the working sleeves or insert the stiffening wire for removal.

Warning: If balloon material is remaining in vertebral body after removal of the VBS balloon do not leave it implanted. The balloon material is not implant grade material.
Cement Augmentation

1

Inject PMMA based bone cement
Additional cement augmentation with a legally marketed PMMA based bone cement adequately indicated for use in vertebroplasty or kyphoplasty procedures is mandatory.

After cavity creation with VBB or VBS, inject PMMA based cement bilaterally.

Insert the side-opening cannulae into the working sleeves. Connect the syringes. The volume of cement required can be estimated from the volume of balloon inflation fluid medium needed for VBB or VBS expansion (1).

It is mandatory to monitor cement flow under real-time x-ray control.

**Warning:** Cement should be injected until it infiltrates the surrounding cancellous bone around the cavity created by the balloon or the stent. For safer cement application, high viscosity cement should be used (2).

**Tip:** The side-opening cement outflow window can be closed by turning the cannula.

It is recommended to use Vertecem V+.

Vertecem V+ is a PMMA based bone cement to treat vertebral compression fractures:
- About 27 minutes of working time
- Excellent X-ray visibility

**Note:** Refer to the manufacturer's directions accompanying the bone cement for specific information on its use, precautions and warnings.
2

Remove side-opening needles and working sleeves
Wait until the cement has fully hardened. Observe the bone cement manufacturer’s instructions as the hardening times for PMMA based cements can greatly vary.

Usually instruments used for the cement injection shall be removed after hardening of PMMA based bone cement by twisting the instrument assembly several times to sever the cement bridge.

Suture the wound with tight stitches for hemostasis.

Postoperative procedure
To compress the wound the patient should be placed in a supine position for an hour after surgery. Bruising may occur at the puncture sites. The patient can then be mobilized at discretion.

Vertebral Body Stent with Balloon

The Vertebral Body Stent with Balloon consists out of a double pack containing one VBS and one corresponding VBB catheter.

The respective sizes are Small, Medium and Large:
09.804.600S  09.804.601S  09.804.602S
VBS Small      VBS Medium   VBS Large
with Balloon   with Balloon with Balloon

The dimensions of the VBS are as described on page 44 and the respective VBB are:

### Contents:
- 2× Cannulae with Side Opening, with Luer lock
- 2× Injection cannulae with Luer lock
- 2× Guide Wires, with Depth Markings
- 2× Trocar
- 2× Cannulated trocar
- 2× Vertebral Body Stent Access Working Sleeve
- 1× Vertebral Body Stent Access Drill
- 1× Vertebral Body Stent Access Plunger

Optional Instruments

399.410       Hammer, 300 g

292.210S      Kirschner Wire Ø 2.0 mm with trocar tip, length 280 mm, Stainless Steel, sterile

Vertecem V+ System

07.702.016S   Vertecem V+ Cement Kit
               Containing:
               1 × Vertecem V+ Mixer pre-filled with cement powder
               1 × Monomer glass ampoule

03.702.215S   Vertecem V+ Syringe Kit
               Containing:
               8 × Blue 1 ml syringes
               5 × White 2 ml syringes
               1 × one-way stop cock
